`blockShape + [batch]`, interleaves these blocks back into the grid\n * defined by the spatial dimensions `[1, ..., M]`,
to obtain a result with\n * the same rank as the input. The spatial dimensions of this intermediate\n * result are then
optionally cropped according to `crops` to produce the\n * output. This is the reverse of `tf.spaceToBatchND`. See

dimension `i`. It is required\n * that `cropStart[i] + cropEnd[i] <= blockShape[i] * inputShape[i + 1]`\n *
This operation is equivalent to the following steps:\n *
1. Reshape `x` to `reshaped` of shape: `[blockShape[0], ..., \n *
blockShape[M-1], batch / prod(blockShape), x.shape[1], ..., \n *
x.shape[N-1]]`\n *

blockShape[0], ..., \n *
x.shape[M], \n * blockShape[M-1], x.shape[M+1], ..., x.shape[N-1]]`\n *
3. Reshape `permuted` to produce `reshapedPermuted` of shape `[batch /\n * prod(blockShape), x.shape[1] *

Computes depthwise 2D convolution, optionally fused with adding a bias and applying an activation.
 Given a 4D `input` array and a `filter` array of shape
 `[filterHeight, filterWidth, inChannels, channelMultiplier]` containing
 `inChannels` convolutional filters of depth 1, this op applies a
 different filter to each input channel (expanding from 1 channel to
 `channelMultiplier` channels for each), then concatenates the results
 together. The output has `inChannels * channelMultiplier` channels.
 See
 https://www.tensorflow.org/api_docs/python/tf/nn/depthwise_conv2d
 for more details.

@param obj An object with the following properties:

- @param x The input tensor, of rank 4 or rank 3, of shape
 `[batch, height, width, inChannels]`. If rank 3, batch of 1 is assumed.
- @param filter The filter tensor, rank 4, of shape
 `[filterHeight, filterWidth, inChannels, channelMultiplier]`.
- @param strides The strides of the convolution:
 `[strideHeight, strideWidth]`. If strides is a single number, then
 `strideHeight == strideWidth`.
- @param pad The type of padding algorithm.
 - `same` and stride 1: output will be of same size as input,
 regardless of filter size.
 - `valid`: output will be smaller than input if filter is larger
 than 1x1.

For more info, see this guide:
 https://www.tensorflow.org/api_guides/python/nn#Convolution

@param dilations The dilation rates:
 `[dilationHeight, dilationWidth]` in which we sample input values
 across the height and width dimensions in atrous convolution.
 Defaults to `[1, 1]`. If `rate` is a single number, then
 `dilationHeight == dilationWidth`. If it is greater than 1, then
 all values of `strides` must be 1.

@param dataType An optional string from:
 `"NHWC"`, `"NCHW"`. Defaults to `"NHWC"`. Specify the data format
 of the input and output data. With the default format
 `"NHWC"`, the data is stored in the order of:
 [batch, height, width,

```

channels]. Only \"NHWC\" is currently supported.\n * @param dimRoundingMode A string from: 'ceil', 'round',
'floor'. If none is\n * provided, it will default to truncate.\n * @param bias Tensor to be added to the result.\n *
@param activation Name of activation kernel (defaults to `linear`).\n * @param preluActivationWeights Tensor of
prelu weights to be applied as part\n * of a `prelu` activation, typically the same shape as `x`.\n * @param
leakyreluAlpha Optional. Alpha to be applied as part of a `leakyrelu`\n * activation.\n */\nfunction

$x - x * z + \log(1 + \exp(-x))$ For $x < 0$, to avoid overflow in $\exp(-x)$, we reformulate the above
 $x * z + \log(1 + \exp(-x)) = \log(\exp(x)) - x * z + \log(1 + \exp(-x)) = -x * z + \log(1 + \exp(x))$
Hence, to ensure stability and avoid overflow, the implementation uses this equivalent formulation:
 $\max(x, 0) - x * z + \log(1 + \exp(-\text{abs}(x)))$

Computes softmax cross entropy between logits and labels.
Measures the probability error in discrete classification tasks in which the classes are mutually exclusive (each entry is in exactly one class).
For example, each CIFAR-10 image is labeled with one and only one label: an image can be a dog or a truck, but not both.
NOTE: While the classes are mutually exclusive, their probabilities need not be. All that is required is that each row of labels is a valid probability distribution. If they are not, the computation of the gradient will be incorrect.
WARNING: This op expects unscaled logits, since it performs a softmax on logits internally for efficiency. Do not call this op with the output of softmax, as it will produce incorrect results.
logits and labels must have the same shape, e.g. [batch_size, num_classes] and the same dtype.
